Conjugates in which a virus is bound via an antibody to a substance having an affinity for nucleic acid, for transporting gene constructs into higher eucaryotic cells. Complexes of the conjugates and nucleic acid are internalized in the cell, whilst the virus as part of the complex brings about the internalization and the release of the contents of the endosomes, in which the complexes are located after entering the cell. Pharmaceutical preparations in which the nucleic acid is a therapeutically active gene construct, particularly for use in gene therapy.

AB Peptides containing a biological-function domain and a medically useful metal ion-binding domain are labeled with medically useful metal ions for use in diagnosis and treatment of a variety of pathologic conditions. The peptides have the amino acid sequence

(R.sub.1)-[Y.sub.1].sub.n-(R.sub.2),

(R.sub.1) - [Y.sub.1 - (R.sub.2) - Y.sub.1].sub.n - (R.sub.3)

and (R.sub.1) - [Y.sub.1 - (R.sub.2) - Y.sub.2].sub.n - (R.sub.3)

wherein the medically useful metal ion-binding domain is [Y.sub.1 ].sub.n, [Y.sub.1 - (R.sub.2)-Y.sub.1 ].sub.n or [Y.sub.1 -(R.sub.2)-Y.sub.2 ].sub.n in which n is a number between 1 and about 6 and Y.sub.1 and Y.sub.2 are amino acids with a sulfur, nitrogen or oxygen which is available for binding to metal ions, or can be made available for binding to metal ions; the biological-function domain is an amino acid sequence containing from 1 to about 20 amino acids located in any one or more of R.sub.1, R.sub.2 or R.sub.3; and those portions of R.sub.1, R.sub.2 and R.sub.3 which are not part of the biological-function domain are amino acid sequences containing from 0 to about 20 amino acids. The resulting product may be stored frozen or lyophilized, with labeling accomplished by the addition of the medically useful metal ions. The medically useful metal ion may be radioactive or paramagnetic, with diagnosis performed by gamma scintigraphy, specific photon emission computerized tomography, positron emission tomography or magnetic resonance imaging.

AB The mucin-type carbohydrate Tn cryptantigen (GalNAc.alpha.1-O-Ser/Thr, where GalNAc is N-acetyl-D-galactosamine) is expressed in many carcinomas, in hemopoietic disorders including the Tn syndrome, and on human immunodeficiency virus (HIV) coat glycoproteins, but is not expressed on normal, differential cells because of the

Page 5 08/541,191

expression of a Tn-processing galactosyltransferase. Using Jurkat T leukemic cells which express high levels of Tn antigen due to deficient Tn galactosylation, the authors have established the Tn antigen-mediated gene transfer and demonstrate the considerable efficiency of this approach. The authors used poly(L-lysine) conjugates of the monoclonal antibody 1E3 directed against the Tn antigen to deliver the luciferase and .beta.-galactosidase reporter genes to Jurkat cells by receptor-mediated endocytosis. Addn. of unconjugated 1E3 reduced transfection efficiency in a concn.-dependent manner and incubation with free GalNAc abolished DNA transfer completely, indicating that gene delivery is indeed mediated by the Tn antigen. Pre-treatment of Jurkat cells with Vibrio cholerae sialidase, which uncovers addnl. Tn antigens, resulted in an improvement of gene transfection. Both human and chicken adenovirus particles attached to the DNA/polylysine complex strongly augmented transgene expression. When the .beta.-galactosidase (lacZ) gene was delivered to Jurkat cells by Tn-mediated endocytosis, up to 60% of the cells were pos. in the cytochem. stain using 5-bromo-4-chloro-3-indolyl-.beta.-Dgalactopyranoside (X-gal) as a chromogenic substrate. The efficiency of the transferrin receptor-mediated DNA uptake into Jurkat cells was comparatively low, although these cells were shown to express considerable amts. of transferrin receptor. The authors show here that a mucin-type carbohydrate antigen mediates highly efficient DNA uptake by endocytosis into Jurkat T cells. This method represents a 50-fold improvement of Jurkat cell transfection efficiency over other phys. gene transfer techniques. Specific gene delivery to primary cancer cells exhibiting Tn epitopes may esp. be desirable in immunotherapy protocols.

DOCUMENT TYPE:

Journal English

LANGUAGE: Cultivation of vascular smooth muscle cells from human artery wall is possible under completely serum-free conditions. The effects of attachment factors on cell spreading and cell proliferation are described in detail as well as routine cultivation methods under serum-free conditions (clone cultures, cell migration, subcultivation by use of an exogenous trypsin inhibitor, cryopreservation, and readaptation of cells). After a careful adaptation period, only 2 (BMS and Ultroser G) of the 4 com. available serum-free media supplements tested were used successfully for a routine cultivation of the smooth muscle cells over several passages. With both supplements cell proliferation rates were comparable with hose obtained in medium contg. 10% fetal calf serum. The addn. of platelet-derived growth factor or transferrin to serum-free cultures had no growth-stimulating effect. The addn. of endothelial cell growth factor isolated from bovine brain caused a significant increase in proliferative activity in cells cultivated with BMS, but not with Ultroser G. Moreover, under the serum-free culture conditions described here, the .gamma.-actin content of the cells is largely reduced (51%) for cells cultivated in Ultroser G, and 12% for cells cultivated in BMS) when compared with cells cultivated under serum-contg. conditions (.gamma.-actin content = 100%). The .alpha.-actin content was obsd. to be unaltered. Even after a careful readaptation of serum-free cultured cells to serum conditions, the .gamma.-actin content remained reduced.

Histamine was coupled to poly(L-glutamate) (PLG) to give a copolymer, poly(glutamylhistamineglutamate) (PHG), with approx. 40% of carboxyl groups in PLG being modified. Unlike either poly(L-histidine) (PLH) or PLG, PHG pptd. only in buffers with pH between 4 and 5. A complex was formed between PHG and poly(L-lysine) (PLL) at pH 7, but it was rapidly dissocd. at

.ltoreq. pH 5. When PHG-linked transferrin (Tf-PHG) was used to deliver a PLL-conjugated [3H]methotrexate ([3H]MTX-PLL) in K562 leukemia cell cultures, an intracellular accumulation of the radioactivity was obsd. These results suggest that a copolymer with both imidazole and carboxyl groups can be useful in the design of acid-sensitive, carrier-mediated drug delivery systems.

Journal-

DOCUMENT TYPE:

LANGUAGE: English

A photolabeling approach for conjugating primary arom. amines to carrier proteins is reported which avoids some of the problems of other conjugation methods and which was used to elicit antibodies against the primary arom. amine hapten. The method described here is of general application for coupling primary arom. amines to the carrier proteins and circumvents many of the problems inherent in the isocyanate or diazocoupling methods. 3-Azido-N-ethylcarbazole (ANEC), the azido analog of 3-amino-N-ethylcarbazole, was conjugated to bovine serum albumin (BSA), human transferrin (TR), thyroglobulin (TH), poly-(lysine

.cntdot.tyrosine), and poly-(lysine

.cntdot.phenylalanine) using std. photolabeling procedures. After

photolysis, the conjugated proteins or polypeptides were sepd. from the unbound products of ANEC photolysis on a Sephadex G-10 column. The conjugated proteins were extd. with isobutanol which demonstrated that approx. 20% of the ANEC was covalently coupled to the protein carriers and that the larger portion of the arom. haptens was non-covalently and hydrophobically bound to the carriers. The ANEC-protein conjugates used for immunization demonstrated a total covalently and non-covalently bound ANEC epitope d. of 90 per BSA, 107 per TR, and 800 per TH mol. Rabbits were immunized with the 3 conjugated proteins and the prodn. of antibody specific for the 3-amino-N-ethylcarbazole hapten was demonstrated by ELISA and by inhibition studies using hapten-carrier conjugates of free hapten. The results demonstrate that antibodies against arom. amine haptens may be raised by immunizing animals with hapten-carrier protein conjugates produced by photolabeling. Since the coupling conditions are very mild and the functional group requirements are so general, most carrier proteins should be suitable for use in this method. Moreover, the method described is rapid and generates only small amts. of waste when compared to the diazocoupling and isocyanate coupling procedures. This coupling methodol. should be useful for producing antibodies against a variety of primary arom. amine carcinogens.

Liposome and lipidic particle formulations of compds. are prepd. by dissolving the compds. in a soln. of liposome-forming lipids in an aprotic solvent such as DMSO, optionally contg. a lipid-solubilizing amt. of a lower alkanol, and injecting the resulting soln. into an aq. soln. The resulting liposome or lipidic particle suspension may be dialyzed or otherwise concd. This method is particularly useful for compds. which are poorly-sol. in aq. soln., but is generally useful for any compd.(s) which can be dissolved in an aprotic solvent or aprotic solvent/lower alkanol mixt. A soln. of doxorubicin (6.2 mM) in an EtOH soln. of egg phosphatidylglycerol-

egg phosphatidylcholine-cholesterol (7:3:6), at a 96.4 mM total lipid concn., was injected in 10 mM tris-HCl (pH 4) contg. 140 mM NaCl. The lipid suspension was dialyzed against the above aq. phase and the encapsulated doxorubicin was sepd. by column chromatog. on Sephadex G-50.

English LANGUAGE:

The authors subverted a receptor-mediated endocytosis event to transport genes into human leukemic cells. By coupling the natural iron-delivery protein transferrin to the DNA-binding polycations polylysine or protamine, protein conjugates were created that bind nucleic acids and carry them into the cell during the normal transferrin cycle (Wagner, E. et al., 1990). This procedure is useful for a human leukemic cell line. The rate of gene delivery was enhanced by (1) increasing the transferrin receptor d. through treatment of the cells with the cell-permeable iron chelator desferrioxamine, (2) interfering with the synthesis of heme with succinyl acetone treatment, or (3) stimulating the degrdn. of heme with cobalt chloride treatment. Consistent with gene delivery as an endocytosis event, the subsequent expression in K-562 cells of a gene included in the transported DNA depends upon the cellular presence of the lysosomotropic agent chloroquine. By contrast, monensin blocks "transferrinfection," as does incubation of the cells at 18.degree..

DOCUMENT TYPE: Journal-LANGUAGE: English OTHER SOURCE(S): CJACS

A novel diastereomeric pair of isomers was discovered in an initial

study of the interaction of the antimetastatic agent trans-RuCl2(DMSO)4, with nucleic acid components. In particular, 5'-dGMP forms 2 products that have characteristic features clearly indicating that the guanine N7 and the .alpha.-phosphate group form a chelate to the metal center. These features include (a) a pronounced downfield shift of the 31P NMR signals of the chelates; (b) a downfield shift of the H8 1H NMR signals of the guanine in the chelates -this downfield shift persists in monodentate N7 coordinate forms favored by protonation of the phosphate group at acid pH; and (c) characteristic changes in the shifts and coupling consts. of the deoxyribose 1H NMR signals. This unusual chelation mode of binding was characterized by NMR spectroscopy in only 2 previous studies. Interestingly, these studies involved other classes of metalloanticancer agents, namely Pt(II) and metallocene drugs. However, in these latter classes of drugs, only 1 isomer was possible. In the Ru derivs. studied here, the octahedral configuration led to the possibility of diastereomers. After sepn. of the chelates by HPLC, the isomers had nearly identical UV absorption spectra and a weak visible band at .apprx.410 nm. However, the CD spectra had bands with opposite signs but similar intensities and positions. Thus, the compds. are isomers that differ principally by having an opposite chirality at Ru. Anal. of several types of expts. demonstrated that the isomers have the compn., [Ru(II)Cl(H2O)(DMSO)2(5'-dGMP)]-. In contrast to the widely studied Pt(II) anticancer agents, the Ru drug does not readily bind to two 5'-dGMP at neutral pH. Thus, in addn. to stereochem. differences between the octahedral Ru(II) and square-planar Pt(II) drugs, the Ru(II) compds. may not easily form the N7,N7 GpG crosslink characteristic of the DNA adducts formed by Pt anticancer drugs. Should the Ru(II) drugs form such a crosslink form, however, 2 diastereomers, with opposite chirality at Ru, are possible.

    Cu complexes of 1,10-phenanthroline (OP-Cu) hydrolyze DNA.
```

Cu complexes of 1,10-phenanthroline (OP-Cu) hydrolyze DNA.

This reaction was studied to det. whether 1,10-phenanthroline (OP) inhibition of the RNA and DNA polymerases result from template hydrolysis or the chelation of a metal assocd. with and essential to the function of these enzymes. Addn. of 4',6-diamino-2-phenylindole-di-HCl (DAPI) to DNA generated a fluorescence signal with a linear increase of the intensity over a broad range of DNA concns. from 0 to 100 .mu.g/mL. The progress of hydrolysis of DNA by DNase I or OP (2 mM) was monitored by the time-dependent decrease in DAPI-induced fluorescence. In the presence of OP, the rate of hydrolysis increased as the Cu2+ concn. in the reaction mixt. rose

from 10-8 to 10-5M. The rate differed for each nucleic acid template used; susceptibility to hydrolysis increased in the order poly(dA-dT) > denatured DNA > double-stranded DNA. However, millimolar amts. of OP did not hydrolyze the template even in the presence of Cu2+ (10-6M) when DNA was complexed with either Escherichia coli DNA polymerase I or E. gracilis or wheat germ RNA polymerase II. Under the same conditions, OP inhibited the activity of both varieties of RNA polymerase II with pKi values of 3.4 and 3.0, resp. The addn. of neocuproine from 10-5 to 10-3 M to chelate any Cu2+ present in the reaction mixt. did not change this inhibition. In contrast, OP did not affect DNA polymerase I. Thus, OP inhibits the enzyme activity of a complex of RNA polymerase with nucleic acid template by chelation of metal atoms essential for the function of these polymerases rather than by hydrolysis of their template. Zn was the only enzymically active metal assocd. with RNA polymerases. This functional role was confirmed further by the demonstration that these enzymes were also inhibited by other chelating agents whose structures differed distinctively from that of OP, including dipicolinic acid, 8-hydroxyquinoline, .alpha.,.alpha.'-bipyridyl, and 8-hydroxyquinoline-5-sulfonic acid.

-English LANGUAGE:

The effect of the Fe chelator desferrioxamine (DFOA) on the expression of transferrin receptors (TfR) by CCRF-CEM human T-cell leukemia and B16 mouse melanoma cells growing in tissue culture were studied. DFOA enhanced TfR expression when added in the dose range of 10-5-10-4M to CCRF-CEM cells, but was toxic to these cells, with the lower concns. producing a slowing of cell growth with a buildup in S-phase, whereas higher concns. caused cell death with a block at the G1/S-phase interface. These toxic effects are compatible with its previously reported inhibition of the nonheme-Fe-contg. (M2) subunit of ribonucleotide reductase. In marked contrast, DFOA caused the growth of B16 melanoma cells to arrest in G1, without loss of cloning efficiency, and resulted in a fall in TfR expression to .apprx.50% of control values. Thus, the effects of DFOA on TfR expression may be linked to DNA synthesis rather than to a more generalized inhibition of Fe-dependent cellular processes. Inhibition of the M2 subunit of ribonucleotide reductase in CCRF-CEM cells with 5 .times. 10-5M hydroxyurea, which is not an Fe chelator, also enhanced TfR expression, as did thymidine and cytosine arabinoside, which have different enzyme targets. By measuring cellular DNA and RNA content simultaneously, it was shown

that all of these agents caused unbalanced growth, i.e., inhibited DNA synthesis more than RNA synthesis.

In contrast, 6-thioguanine was more inhibitory to RNA synthesis, and treatment with this drug caused a fall in TfR expression. Thus, although CCRF-CEM cells treated with DFOA show enhanced TfR expression, similar effects are also seen with other inhibitors of DNA synthesis, provided that RNA synthesis is allowed to continue. These results provide

further evidence that the regulation of TfR expression by proliferating cells is specifically linked to DNA synthesis rather than to the Fe requirements of other cellular processes.

English LANGUAGE:

In is essential for cellular proliferation. In deficiency of E. gracilis results in arrest of cell division and deranges

nucleic acid and protein metab., pointing to a decisive role of Zn in transcription and translation. Therefore, the role of Zn was investigated in the function of the DNA -dependent RNA polymerases (I) of this organism. Two I from Zn-sufficient organisms were purified by affinity chromatog. on a DNA-cellulose column and subsequently sepd. on DEAE-Sephadex A-25. The 2 fractions were characterized as I I and II by their elution pattern from DEAE-Sephadex and sensitivity to .alpha.-amanitin. I II has a provisional mol. wt. of 700,000 and contains an av. of 2.2 g-atoms of Zn/mole of enzyme, but no Mn, Cu, or Fe, as measured by microwave emission spectroscopy.

Chelating agents, such as 1,10-phenanthroline (II), 8-hydroxyquinoline, 8-hydroxyquinoline-5-sulfonic acid, and lomofungin, inhibit activity. In contrast, the nonchelating analogs, 1,7- and 4,7-phenanthroline, do not affect activity. Inhibition by II is instantaneous and fully reversible by diln. II also inhibits I I, suggesting a role of Zn in its function. The demonstration that I II is a Zn enzyme indicates the involvement of Zn in eukaryotic RNA synthesis and serves as a further basis for the definition of the role of this element in eukaryotic cell growth, division, and differentiation.

Monolayers of baby-hamster kidney cells were grown on glass in tissue culture and harvested with trypsin or EDTA in order to investigate the cell surface macromols. removed by these cell-disaggregating agents. The release of

nucleic acids from the cells during the harvesting procedure was monitored by labeling the cellular RNA with uridine-5-3H and the cellular DNA with thymidine-2-14C. Treatment of the cells with EDTA caused an increase in the permeability of the plasma membrane with 7.6% of the cellular

RNA, but less than 1% of the cellular DNA, being released. Moreover, 61% of the cells harvested with EDTA were permeable to trypan blue. With crude trypsin, lysis of the cell occurred with the release of similar amts. of RNA and

DNA amounting to about 11% of the total cellular

nucleic acid. In contrast cryst.

trypsin released only 1% of the cellular nucleic acids. Since virtually all the cells (99%) after harvesting in cryst. trypsin were impermeable to trypan blue, this method was suitable for obtaining cell surface macromols. without contamination by intracellular damage. Glucosamine-1-14C was incorporated by the cells only into bound hexosamines and sialic acids. By monitoring the release of radioactivity in high-mol.-wt. material in such expts. a measure of the release of macromols. contg. amino sugars was obtained. Of the total macromols. contg. amino sugars in the cells 33%, 24% and 13% were released when the cells were harvested with crude trypsin, cryst. trypsin or EDTA, resp. Cryst. trypsin also released 39% of the total sialic acid of the cell, whereas less than 1% of the cellular sialic acid was present in the EDTA-treated fraction. The macromols. contg. amino sugars released with crude trypsin and EDTA are likely to be heavily contaminated with intracellular material. However, the macromols. released by cryst. trypsin appear to come from the cell surface.

LANGUAGE: English

The exposure of sarcoma 180 ascites cells to the cupric chelate [Cu(II)KTS] of kethoxal bis(thiosemicarbazone) (KTS) resulted in the death of a large proportion of the cell population; both the ligand portion of the mol., KTS, and CuCl2 were less toxic. Cells isolated from mice treated with Cu(II)KTS contained considerably greater amts. of Cu than did those cells exposed to the same no. of gram-atoms of Cu presented as either CuCl2 or Cu stearate. The relatively lipid-sol. chelate-form of Cu was evidently more readily assimilated. Dissocn. of Cu(II)KTS occurred within neoplastic cells, and this resulted in a relatively rapid loss from the cells of the ligand portion, KTS. In contrast, the Cu derived from Cu(II)KTS persisted for a much

longer period of time. The relation of nucleic acid and protein synthesis to the phenomenon of cell death

induced by these agents was assessed by measuring the effects of the compds. on these metabolic processes. The formation of DNA was more sensitive to the inhibitory action of Cu(II)KTS, CuCl2, and KTS, than were either the syntheses of RNA or protein. In agreement with the cellular toxicity, Cu(II)KTS caused more pronounced depression of the incorporation of isotopic precursors into DNA than did either CuCl2 or KTS. The Cu present in cells treated with Cu(II)KTS induced at least 3 metabolic blocks on the pathways of DNA biosynthesis. The most sensitive site was measured by the incorporation of thymidine-3H into DNA and presumably was the result of the loss of activity of thymidine kinase. The findings obtained using a variety of isotopic precursors of DNA as biochem. probes suggested that the intracellular localization of Cu derived from Cu(II) KTS differed from that of CuCl2. 28 references.

AB A novel diastereomeric pair of isomers was discovered in an initial? study of the interaction of the antimetastatic agent trans-RuCl2(DMSO)4 with nucleic acid components. In particular, 5'-dGMP forms two products that have characteristic features clearly indicating that the guanine N7 and the .alpha.-phosphate group form a chelate to the metal center. These features include (a) a pronounced downfield shift of the 31P NMR signals of the chelates; (b) a downfield shift of the H8 1H NMR signals of the guanine in the chelates-this downfield shift persists in monodentate N7 coordinated forms favored by protonation of the phosphate group at acid pH; and (c) characteristic changes in the shifts and coupling constants of the deoxyribose 1H NMR signals. This unusual chelation mode of binding has been characterized by NMR spectroscopy in only two previous studies. Interestingly, these studies involved other classes of metalloanticancer agents, namely Pt(II) and metallocene drugs. However, in these latter classes of drugs, only one isomer was possible. In the Ru derivatives studied here, the octahedral configuration leads to the possibility of diastereomers. After separation of the chelates by HPLC, the isomers were found to have nearly identical UV absorption spectra and a weak visible band at .apprx.410 nm. However, the CD spectra have bands that have

opposite signs but similar intensities and positions. Thus, the compound are isomers that differ principally by having an opposite chirality at ruthenium. Analysis of several types of experiments demonstrated that the isomers have the composition [RuIICl(H2O)(DSMO)2(5'-dGMP)]-. In contrast to the widely studied Pt(II) anticancer agents, the Ru drug does not readily bind to two 5'-dGMP at neutral pH. Thus, in addition to stereochemical differences between the octahedral Ru(II) and square-planar Pt(II) drugs, the Ru(II) compounds may not easily form the N7,N7 GpG crosslink characteristics of the DNA adducts formed by Pt anticancer drugs. Should the Ru(II) drugs form such a crosslink form, however, two diastereomers, with opposite chirality at Ru, are possible.

AB Copper complexes of 1,10-phenanthroline (OP-Cu) hydrolyze DNA

[D'Aurora, V., Stern, A. M., & Sigman, D. S. (1978) Biochem. Biophys. Res. Commun. 80, 1025-1032; Marshall Pope, L., Reich, K. A., Graham,

D. R., & Sigman, D. S. (1982) J. Biol, Chem. 257, 12121-12128]. This

reaction has been studied to determine whether the

1,10-phenanthroline (OP) inhibition of the activity of RNA

and DNA polymerases is the result of template hydrolysis or

the chelation of a metal associated with and essential to

the function of these enzymes. Addition of 4',6-diamino-2-

phenylindole dihydrochloride (DAPI) to DNA generates a

fluorescence signal with a linear increase of the intensity over a

broad range of DNA concentrations from 0 to 100 .mu.g/mL.

The progress of hydrolysis of DNA by DNase I or OP (2 mM)

is monitored by the time-dependent decrease in DAPI-induced

fluorescence. In the presence of OP, the rate of hydrolysis increases as the Cu2+ concentration in the reaction mixture arises from 10-8 to

10-5 M. The rate differs for each nucleic acid

template used; hydrolysis of poly(dA-dT) > denatured DNA >

double-stranded DNA. However, millimolar amounts of OP do

not hydrolyze the template even in the presence of Cu2+ (10-6 M) when

DNA is complexed with either Escherichia coli DNA

polymerase I or Euglena gracilis or wheat germ RNA

polymerase II. Under the same conditions, OP inhibits the activity of

both varieties of RNA polymerase II with pKi's of 3.4 and

3.0, respectively. The addition of neocuproine from 10-5 to 10-3 M to

chelate any Cu2+ present in the reaction mixture does not

change this inhibition. In contrast, OP does not affect

DNA polymerase I activity. Thus, OP inhibits enzyme activity

of a complex of RNA polymerase with nucleic

acid template by chelation of metal atoms essential

for the function of these polymerases rather than by hydrolysis of their template. Zinc is the only enzymatically active metal

associated with RNA polymerases. This functional role is

confirmed further by the demonstration that these enzymes are also

inhibited by other chelating agents whose structures differ distinctively from that of OP: dipicolinic acid, 8-hydroxyquinoline, .alpha..alpha.'-bipyridyl, and 8-hydroxyquinoline-5-sulfonic acid.

English AB The effects of the Fe chelator, deferrioxamine on the

expression of transferrin receptors (TfR) by CCRF-CEM human T-cell leukemia and B16 mouse melanoma cells growing in tissue culture were investigated. Deferrioxamine (DFOA) enhanced TfR expression when added in the dose range of 10-5-10-4 to CCRF-CEM cells, but was toxic to these cells; the lower concentrations produced a slowing of cell growth with a build up in S-phase, while higher concentrations caused cell death with a block at the G1/S-phase interface. These toxic effects are compatible with its previously reported inhibition of the non-heme-Fe containing (M2) subunit of ribonucleotide reductase. In marked contrast, DFOA caused the growth of B16 melanoma cells to arrest in G1, without loss of cloning efficiency, and resulted in a fall in TfR expression to .apprx. 50% of control values. The effects of DFOA on TfR expression were evidently linked to DNA synthesis rather than to a more generalized inhibition of Fe-dependent cellular processes. Inhibition of the M2 subunit of ribonucleotide reductase in CCRF-CEM cells with 5 .times. 10-5 M hydroxyurea, which is not an Fe chelator, also enhanced TfR expression, as did thymidine and cytosine arabinoside, which have different enzyme targets. By measuring cellular DNA and RNA content simultaneously, all of these agents evidently caused unbalanced growth, i.e., inhibited DNA synthesis more than RNA synthesis. In contrast, 6-thioguanine was more inhibitory to RNA synthesis; treatment with this drug caused a fall in TfR expresion. Although CCRF-CEM cells treated with DFOA show enhanced TfR expression, similar effects are also seen with other inhibitors of DNA synthesis, provided that RNA synthesis is allowed to continue. These results provide further evidence that the regulation of TfR expression by proliferating cells is specifically linked to DNA synthesis rather than to the Fe requirements of other cellular processes.

Iron regulates synthesis of the iron storage protein ferritin at the translational level through interaction between a stem-loop structure, the iron-responsive element (IRE), located in the 5'-untranslated region (5'-UTR) of ferritin mRNAs, and a protein, the iron regulatory protein (IRP). The role of IRE secondary structure in translational regulation of ferritin synthesis was explored by introducing ferritin constructs containing mutations in the IRE into Rat-2 fibroblasts. Our in vivo studies demonstrate that size and sequence of the loop within the IRE and the distance and/or spatial relationship of this loop to the bulged nucleotide region closest to the loop must be preserved in order to observe iron-dependent translation of ferritin mRNA. In contrast, changes in nucleotide sequence of the upper stem can be introduced without affecting translational regulation in vivo, as long as a stem can be formed. Our in vivo results suggest that only a very small variation in the affinity of interaction of IRP with IRE can be tolerated in order to maintain iron-dependent regulation of translation.

ENTRY MONTH: 9104

Self-cleavage of a polyribonucleotide containing an autocleaving sequence from the genomic strand of hepatitis delta virus was enhanced by conditions that destabilized RNA structure. Self-cleavage of the transcripts used in this study required Mg2+ (or another divalent cation), and in the absence of denaturants, maximum cleavage was observed at very low Mg2+ concentrations (0.05-0.1 mM). However, at 37 degrees C and in the presence of 2-10 mM Mg2+ the rate of cleavage was increased as much as 50-fold with the addition of urea to 5 M or formamide to 10 M. Cleavage was prevented by higher concentrations of the same reagents (9.5 M urea or 22.5 M formamide), presumably because a structure required for self-cleavage is disrupted by strongly denaturing conditions. In

contrast to a previous report [Wu, H.-N., & Lai, M. M. C.
 (1989) Science 243, 652-654], we find that chelating Mg2+
 with EDTA terminates the cleavage reaction without promoting
 measurable amounts of ligation of the cleavage products. The ability
 of denaturants to promote rapid self-cleavage in vitro raises the
 possibility that an unidentified factor could have a similar effect
 in vivo.

ENTRY MONTH:
     We have subverted a receptor-mediated endocytosis event to transport
     genes into human leukemic cells. By coupling the natural
     iron-delivery protein transferrin to the DNA-binding
     polycations polylysine or protamine, we have created protein
     conjugates that bind nucleic acids and carry
     them into the cell during the normal transferrin cycle [Wagner, E.,
     Zenke, M., Cotten, M., Beug, H. & Birnstiel, M. L. (1990) Proc.
     Natl. Acad. Sci. USA 87, 3410-3414]. We demonstrate here that this
     procedure is useful for a human leukemic cell line. We enhanced the
     rate of gene delivery by (i) increasing the transferrin receptor
     density through treatment of the cells with the cell-permeable iron
   chelator desferrioxamine, (ii) interfering with the
     synthesis of heme with succinyl acetone treatment, or (iii)
     stimulating the degradation of heme with cobalt chloride treatment.
     Consistent with gene delivery as an endocytosis event, we show that
     the subsequent expression in K-562 cells of a gene included in the
     transported DNA depends upon the cellular presence of the
     lysosomotropic agent chloroquine. By contrast,
     monensin blocks "transferrinfection," as does incubation of the
     cells at 18 degrees C.

     Zinc is essential for cellular proliferation. Zinc deficiency of
     Euglena gracilis results in arrest of cell division and deranges
   nucleic acid and protein metabolism pointing to a
     decisive role of zinc in transcription and translation. We have,
     therefore, investigated the role of zinc in the function of the
   DNA-dependent RNA polymerases of this organism.
     Two RNA polymerases from zinc sufficient organisms were
     purified first by affinity chromatography on a DNA
     cellulose column and subsequently separated on diethylaminoethyl
     (DEAE)-Sephadex A-25. The two fractions were characterized as
     polymerase I and II by their elution pattern from DEAE-Sephadex and
     sensitivity to alpha-amanitin. RNA polymerase II has a
     provisional molecular weight of 700 000 and contains an average of
     2.2 g=atoms of zinc per mol of enzyme, but not Mn, Cu, or Fe, as
```

agents, such as 1,10-phenanthroline, 8-hydroxyquinoline,
8-hydroxyquinoline-5-sulfonic acid, and lomofungin, inhibit
activity. In contrast, the nonchelating analogues, 1,7-and
4,7-phenanthroline, do not affect activity. Inhibition by
1,10-phenanthroline is instantaneous and fully reversible by

measured by microwave emission spectroscopy. Chelating

dilution. 1,10-Phenanthroline also inhibits RNA polymerase I, suggesting a role of zinc in its function. The demonstration that RNA polymerase II is a zinc enzyme indicates the involvement of zinc in eukaryotic RNA synthesis and serves as a further basis for the definition of the role of this element in eukaryotic cell growth, division, and differentiation.

CAS INDEXING IS AVAILABLE FOR THIS PATENT.

The present invention relates to the .beta.-glucuronidase (GUS) gene fusion system, and to the cloning and characterization of the .beta.-glucuronidase and glucuronide permease genes of Escherichia coli. It is based on the surprising discovery that gene fusions comprising the .beta.-glucuronidase gene may be effectively expressed in a wide variety of organisms to produce active .beta.-glucuronidase enzyme. Because of the abundance and availability of useful substrates for .beta.-glucuronidase enzyme, GUS gene fusions may serve as a superior reporter gene system as well as an effective means of altering cellular phenotype. In conjunction with recombinant glucuronide permease, which may be used to render host cells permeable to .beta.-glucuronidase substrates, the GUS gene fusion system offers almost unlimited applications in the fields of plant and animal genetic engineering.

Cuantitation of gamma and x-ray emitting isotopes

### ABSTRACT:

For isotopes decaying by capture of an inner shell electron by the nucleus, coincident emission of X-ray and gamma photons may occur. The X-ray results from the drop of an outer shell electron to fill the S shell. The gamma results from the transition of the excited daughter nucleus to a lower energy state. The invention disclosed is a Coincident Gamma and X-ray Detector (CGXD) which achieves extraordinary background rejection by a synergistic combination of coincident counting and other background suppression measures. Whereas the background registered by single gamma counters is of the order of 20-40 counts per minute, a CGXD optimized for the electron capture radioisotope I.sup.125 has a background of about one count per day. 5,527,885 [IMAGE AVAILABLE] L10: 7 of 38 US PAT NO: Bifunctional isothiocyanate derived thiocarbonyls as TITLE: ligands for metal binding

# ABSTRACT:

This invention relates to \*\*chelating\*\* agents useful for coupling metal ions to biologically active molecules. In particular, isothiocyanate derived thiocarbonyls for \*\*chelating\*\* metals such as technetium are provided that can be conjugated to a targeting molecule such as an antibody, a peptide or a protein.

TITLE: Dense star polymer conjugates

## ABSTRACT:

Dense star polymer conjugates which are composed of at least one dendrimer in association with at least one unit of a carried agricultural, pharmaceutical, or other material have been prepared. These conjugates have particularly advantageous properties due to the unique characteristics of the dendrimer.

US PAT NO: 5,521,288 [IMAGE AVAILABLE] L10: 9 of 38 TITLE: CD28IG fusion protein

### ABSTRACT:

The invention identifies the B7 antigen as a ligand that is reactive with the CD28 receptor on T cells. Fragments and derivatives of the B7 antigen and CD28 receptor, including fusion proteins having amino acid sequences corresponding to the extracellular domains of B7 or CD28 joined to amino

acid sequences encoding portions of human immunoglobulin C.gamma.1, are described. Methods are provided for using B7 antigen, its fragments and derivatives, and the CD28 receptor, its fragments and derivatives, as well as antibodies and other molecules reactive with B7 antigen and/or the CD28 receptor, to regulate CD28 positive T cell responses, and immune responses mediated by T cells. The invention also includes an assay method for detecting ligands reactive with cellular receptors mediating intercellular adhesion.

US PAT NO: 5,518,888 [IMAGE AVAILABLE] L10: 10 of 38 TITLE: ST receptor binding compounds and methods of using the

## ABSTRACT:

Conjugated compounds which comprises an ST receptor binding moiety and a radiostable active moiety are disclosed. Pharmaceutical compositions comprising a pharmaceutically acceptable carrier or diluent, and a conjugated compound which comprises an ST receptor binding moiety and a radiostable active moiety or an ST receptor binding moiety and a radioactive active moiety are disclosed. Methods of treating an individual suspected of suffering from metastasized colorectal \*\*cancer\*\* comprising the steps of administering to said individual a pharmaceutical composition comprising a pharmaceutically acceptable carrier or diluent, and a therapeutically effective amount of a conjugated compound which comprises an ST receptor binding moiety and a radiostable active moiety or an ST receptor binding moiety and a radiostable active moiety are disclosed. Methods of radioimaging metastasized colorectal \*\*cancer\*\* cells comprising the steps of first administering to an individual suspected of having metastasized colorectal \*\*cancer\*\* cells, a pharmaceutical composition that comprises a pharmaceutically acceptable carrier or diluent, and conjugated compound that comprises an ST receptor binding moiety and a radioactive active moiety wherein the conjugated compound is present in an amount effective for diagnostic use in humans suffering from colorectal \*\*cancer\*\* and then detecting the localization and accumulation of radioactivity in the individual's body are disclosed. (5,457,183 [IMAGE AVAILABLE] L10: 11 of 38 US PAT NO: Mydroxylated texaphyrins TITLE:

## ABSTRACT:

A method of using texaphyrins as radiosensitizers. Advantageous properties of texaphyrins for use as a radiosensitizer include i) a low redox potential which allows radiation induced solvated electrons to flow to texaphyrin rather than neutralizing hydroxyl radicals, allowing the hydroxyl radicals to cause cellular damage, ii) a relatively stable texaphyrin radical which, nevertheless, reacts readily to covalently modify neighboring molecules causing further cellular damage, and iii) intrinsic biolocalization and indifference to the presence of O.sub.2 which allow texaphyrin to be particularly effective for treating the hypoxic areas of solid \*\*tumors\*\*. Sensitizer enhancement ratios of 1.62 and 2.2 were achieved at 20 .mu.M and 80 .mu.M gadolinium-texaphyrin, respectively, with a mouse leukemia cell line. Methods of treatment for an individual having a \*\*tumor\*\* include the use of a texaphyrin as a radiosensitizer and as an agent for photodynamic \*\*tumor\*\* therapy, or the use of a texaphyrin for internal and for external ionizing radiation. New water soluble hydroxy substituted texaphyrins are described. ( 5,449,761 [IMAGE AVAILABLE] L10: 12 of 38 US PAT NO: Metal-binding targeted polypeptide constructs TITLE:

# ABSTRACT:

This invention relates to the preparation and use of novel open-chain or cyclic polypeptide constructs in which two or more polypeptide chains, in an open-chain construct, or one or more chains, in a cyclic construct,

are chemically derivatized such that the resulting construct exhibits both metal-binding capability and tissue-, organ- or cell-targeting selectivity. In particular, the polypeptide constructs of the present invention comprise compounds of the formula (I): ##STR1## in which, "B" is a hydrocarbon backbone, "P" is a polypeptide capable of targeting particular cells, tissues or organs of the body, "A" may be the group --NR'--NR"-- or the group --NR'--NR"--L-- in which L may be an aliphatic r salt thereof which is spectroscopically or photoactively determinable when bound to \*\*DNA\*\* having the formula ##STR1## wherein M is a suitable transition metal and each of R.sub.1, R.sub.2 and R.sub.3 is ethylenediamine or a substituted derivative thereof, bipyridine or a substituted derivative thereof, phenanthroline or a substituted derivative thereof, diazfluorene-9-one or a substituted derivative thereof, phenanthrenequinonediimine or a substituted derivative thereof; wherein R.sub.1, R.sub.2 and R.sub.3 are bound to M by coordination bonds wherein R.sub.1 and R.sub.2 are the same and both are different from R.sub.3. The invention also concerns a method of labeling \*\*DNA\*\* with the coordination complex, a \*\*DNA\*\* molecule

labeled with the coordination complex, a method of selectively labeling \*\*DNA\*\* conformation with the coordination complex and a method of detecting the presence of a conformation present in a double stranded

\*\*DNA\*\*.

Apolipoprotein B MRNA editing protein compositions and

methods

## ABSTRACT:

TITLE:

The present invention provides a protein that edits apo B \*\*RNA\*\*. A polynucleotide that comprises a \*\*DNA\*\* sequence that encodes an apo B \*\*RNA\*\* editing protein and an expression vector comprising such a polynucleotide are also provided. Processes for producing an apo B \*\*RNA\*\* editing protein, editing apo B \*\*RNA\*\* and altering apo B protein production are also provided.

US PAT NO: 5,420,245 [IMAGE AVAILABLE] L10: 15 of 38 TITLE: Tetrapeptide-based inhibitors of farnesyl transferase

# ABSTRACT:

Disclosed are methods and compositions for the identification, characterization and inhibition of mammalian farnesyl protein transferases, enzymes involved in the farnesylation of various cellular proteins, including \*\*cancer\*\* related ras proteins such as p21.sup.ras.-One farnesyl protein transferase which is disclosed herein exhibits a molecular weight of between about 70,000 and about 100,000 upon gel exclusion chromatography. Also disclosed are methods and compositions for the preparation of farnesyl transferase by recombinant means, following of proteins such as p21.sup.ras. Also disclosed is a families of compounds which act either as false substrates for the enzyme or as pure inhibitors and can therefore be employed for inhibition of the enzyme. The most potent inhibitors are ones in which phenylalanine occurs at the third position of a tetrapeptide whose amino terminus is cysteine. US PAT NO: 5,420,244 [IMAGE AVAILABLE] L10: 16 of L10: 16 of 38 Methods and compositions for diagnosing HTLV-I associated TITLE: myelopathy and adult T-cell leukemia

### ABSTRACT:

The invention provides antigenic peptides derived from immunodominant epitopes of the HTLV-I tax or rex proteins that are immunoreactive with antibodies associated with disease in HTLV-I infected subjects. More specifically, the invention provides antigenic peptides consisting essentially of the amino acid sequences defined in the sequence listing by SEQ ID NOS: 1, 2, 3, 4, 5, 6, 7 and 8 and antigenic fragments thereof.

Page 7 08/541,191

The invention provides a method of diagnosing HTLV-I associated myelopathy (HAM) or a predisposition thereto, comprising the steps of: (a) contacting an antibody containing sample from the subject with a detectable amount of a peptide of the invention or an antigenic fragment thereof; and (b) detecting the reaction of the peptide with an antibody in the sample, the reaction indicating HTLV-I associated myelopathy or a predisposition thereto. The invention also provides a method of diagnosing adult T-cell leukemia or a predisposition thereto in a subject, comprising the steps of: (a) contacting an antibody containing sample from the subject with a detectable amount of the peptide of SEQ ID NO: 1; and (b) detecting the reaction of the peptide with an antibody in the sample, the reaction indicating adult T-cell leukemia or predisposition thereto. 5,416,192 [IMAGE AVAILABLE] L10: 17 of 38 US PAT NO: Epithelins: povel cysteine-rich growth modulating proteins TITLE:

### ABSTRACT:

A novel family of growth regulatory proteins termed "epithelins" are described. The epithelins comprise several distinct members sharing significant structural homology. Two members of the epithelin family, epithelin 1 and epithelin 2, have been purified from natural sources. In addition, cDNA and PCR clones encoding mature and precursor epithelins from various chordate sources have been obtained and sequenced, including the complete human, mouse and rat epithelin precursors. The recombinant expression of rat epithelin precursor and mature forms is described. Purified epithelin 1 is a bifunctional growth regulator, capable of stimulating the growth of some cell types while inhibiting the growth of others. Purified epithelin 2 is functionally similar to epithelin 1 with respect to growth inhibitory bioactivity. In \*\*contrast\*\*, however, epithelin 2 is apparently not capable of eliciting the growth stimulatory activity characteristic of epithelin 1 and, in fact, antagonizes this epithelin/1 activity. 5,373,093 [AMAGE AVAILABLE] L10: 18 of 38 US PAT NO: / Macrocyclic complexes of yttrium, the lanthanides and the TITLE: actimides having peripheral coupling functionalities

# ABSTRACT:

Functionalized water soluble macrocyclic complexes of lanthanide, actinide and yttrium ions were obtained by metal templated, Schiff-base, cyclic condensation of: (1) a functionalized 1,2-diaminoethane and a dicarbonyl compound selected from the group consisting of 2,6-dicarbonylpyridine, 2,6-diformylpyridine, 2,5-dicarbonylfuran, 2,5-diformylfuran, 2,5-dicarbonylthiophene and 2,5-diformylthiophene; or (2) 1,2-diaminoethane and a ring-substituted heterocyclic dicarbonyl compound selected from a group consisting of substituted 2,6-dicarbonylpyridine, substituted 2,6-diformylpyridine, substituted 2,5-dicarbonylfuran, substituted 2,5-diformylfuran; substituted 2,5-dicarbonyl thiophene, and substituted 2,5-diformylthiophene. Coordination complexes thus formed are kinetically stable in dilute aqueous solution. They are further reacted, or coupled, through a substituent on the 1,2-diaminoethane or on the pyridine, furan, or thiophene moieties, to one of the following: proteinaceous materials, polysaccharides, other biologically compatible macromolecules or bridging molecules which, can be further reacted or coupled to the above mentioned substrates. These macrocyclic complexes are suitable in the preparation of reporter molecules and for magnetic resonance, radiation \*\*imaging\*\* and radiation therapy. 5,362,629 [IMAGE AVAILABLE] L10: 19 of 38 US PAT NO: Detection of immunosuppressants

TITLE:

A method of evaluating the immunosuppressive activity of a compound including contacting the compound with calcineurin and determining the ability of the compound to bind to the calcineurin. The ability to bind to the calcineurin is positively correlated to the immunosuppressive activity of the compound.

Immunoassays for the detection of antibodies to HCV are provided which employ "C" domain antigens. Immunoassay kits comprising such antigens are also provided.

US PAT NO: 5,346,670 [IMAGE AVAILABLE] L10: 21 of 38

TITLE: Phthalocyanine and tetrabenztriazaporphyrin reagents

HGV immunoassays employing C domain antigens

#### ABSTRACT:

Red-shifted, water-soluble, fluorescent, monomerically-tetherable derivatives having the formula: ##STR1## wherein, M represents either H.sub.2 or is selected from among the following metals: aluminum, silicon, phosphorus, gallium, germanium, cadmium, scandium, magnesium, tin, and zinc. Each R.sub.1 is independently selected from --XYW, --YW, and --W. X represents either a carbon, or heteroatom selected from among oxygen, nitrogen, sulfur, phosphorus, silicon, and selenium; Y represents a linking group; and W represents a water solubilizing group. The substituent R.sub.2 is selected from among --A, --Y'A, --XA, and --XY'A, where A denotes a biological entity such as an antibody, antibody fragment, nucleotide, \*\*nucleic\*\* \*\*acid\*\* probe, antigen, oligonucleotide, deoxynucleotide, dideoxynucleotide, avidin, streptavidin or membrane probe, or R.sub.2 is a reactive or activatable group suitable for conjugating to a biological entity. Y' is a linking group that tethers the biological entity to the phthalocyanine or tetrabenztriazaporphyrin macrocycle. Z is either a nitrogen atom or a carbon substituted with hydrogen, alkyl, aryl, or aralkyl groups. Z may also be attached to R.sub.2. Also disclosed are derivatives of the compounds of the above Formula in which 1-4 of the benzo ring(s) contain 1 or 2 N atoms. Methods of sequencing \*\*DNA\*\* and detecting analytes, including cells, using these derivatives are disclosed, as are kits for carrying out assays for the analytes and flow cytometry. Methods of detecting \*\*DNA\*\* using cationic compounds of the above Formula, wherein R.sub.2 = R.sub.1 and W = - N.sup. + D.sub.1 D.sub.2 D.sub.3 are also disclosed. Further, compounds containing Tc, Gd, etc. as the metal in the above formula may be used for \*\*imaging\*\* or therapy. L10: 22 of 38 5,328,840 [XMAGE AVAILABLE] US PAT NO: Method for preparing targeted carrier erythrocytes TITLE:

## ABSTRACT:

The present invention provides new compounds and methods for promoting platelet aggregation, and controlling bleeding. The present invention is based on the surprising discovery that erythrocytes conjugated to certain peptides and polypeptides containing an R-G-D (Arg-Gly-Asp) sequence (collectively termed herein "RGD peptides") according to the invention, selectively bind to activated platelets but not to unactivated platelets. In recognition of the dual nature of the derivatized erythrocytes, they are termed herein "thrombo-erythrocytes". The thrombo-erythrocytes have no significant change in their rheological properties. In a preferred aspect, the thrombo-erythrocytes have the majority of RGD peptide cross-linked specifically to glycophorin A and glycophorin B on the surface of the erythrocyte. In the thrombo-erythrocytes of the invention, preferably, the N-terminal Arg of the R-G-D sequence should be spaced within 9-50 Angstroms, more preferably 10-40 Angstroms, and most preferably 11-25 Angstroms, from the erythrocyte protein to which the RGD

peptide is conjugated. The invention is further directed to erthrocytes modified by replacement of their intracellular contents with a composition comprising a label or agent. Such modified erythrocytes are termed herein "carrier erythrocytes". The carrier erythrocytes have use in delivery of such labels or biologically active agents to specific tissues by conjugation to a targeting agent.

US PAT NO: 5,326,856 [IMAGE AVAILABLE] L10: 23 of 38 Eigunctional isothiocyanate derived thiocarbonyls as ligands for metal binding

#### ABSTRACT:

This invention relates to \*\*chelating\*\* agents useful for coupling metal ions to biologically active molecules. In particular, isothiocyanate derived thiocarbonyls for \*\*chelating\*\* metals such as technetium are provided that can be conjugated to a targeting molecule such as an antibody, a peptide or a protein.

TITLE: Biosynthetic antibody binding sites

## ABSTRACT:

Disclosed are a family of synthetic proteins having affinity for a preselected antigen. The proteins are characterized by one or more sequences of amino acids constituting a region which behaves as a biosynthetic antibody binding site (BABS). The sites comprise 1) non-covalently associated or disulfide bonded synthetic V.sub.H and V.sub.L dimers, 2) V.sub.H -V.sub.L or V.sub.L -V.sub.H single chains wherein the V.sub.H and V.sub.L are attached by a polypeptide linker, or 3) individuals V.sub.H or V.sub.L domains. The binding domains comprise linked CDR and FR regions, which may be derived from separate immunoglobulins. The proteins may also include other polypeptide sequences which function e.g., as an enzyme, toxin, binding site, or site of attachment to an immobilization media or radioactive atom. Methods are disclosed for producing the proteins, for designing BABS having any specificity that can be elicited by in vivo generation of antibody, and for producing analogs thereof.
